

Oracle ZFSSA active/active mode

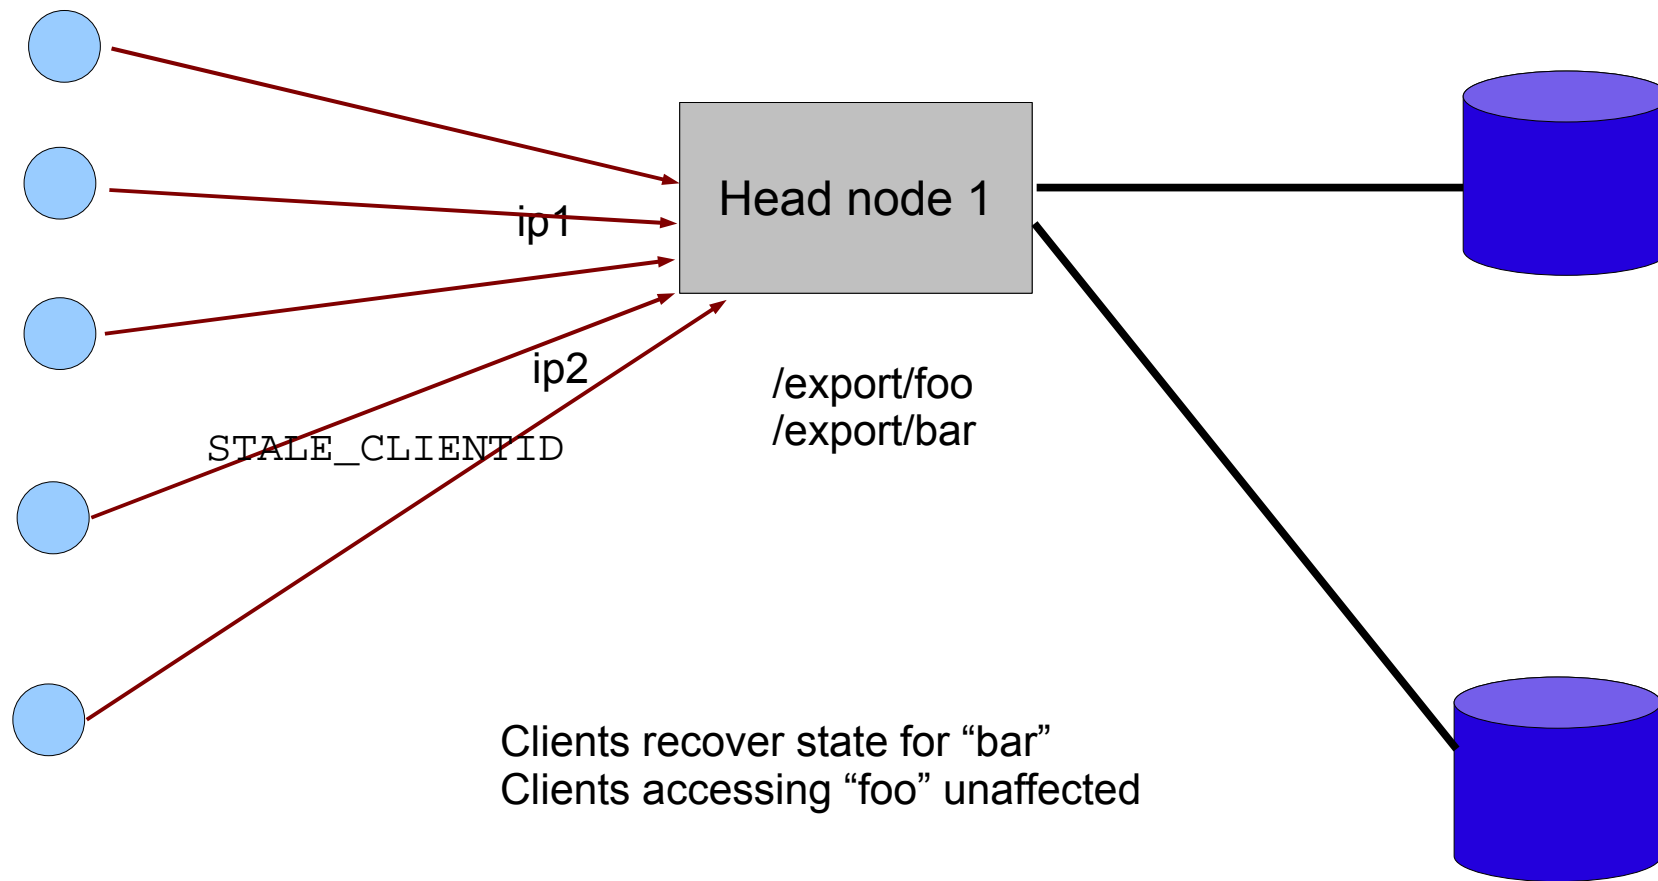

Oracle ZFSSA active/active mode, head node 2 fails

Oracle ZFSSA active/active mode, head node 1 takes over resources

Oracle ZFSSA active/active mode, clients recover

clients

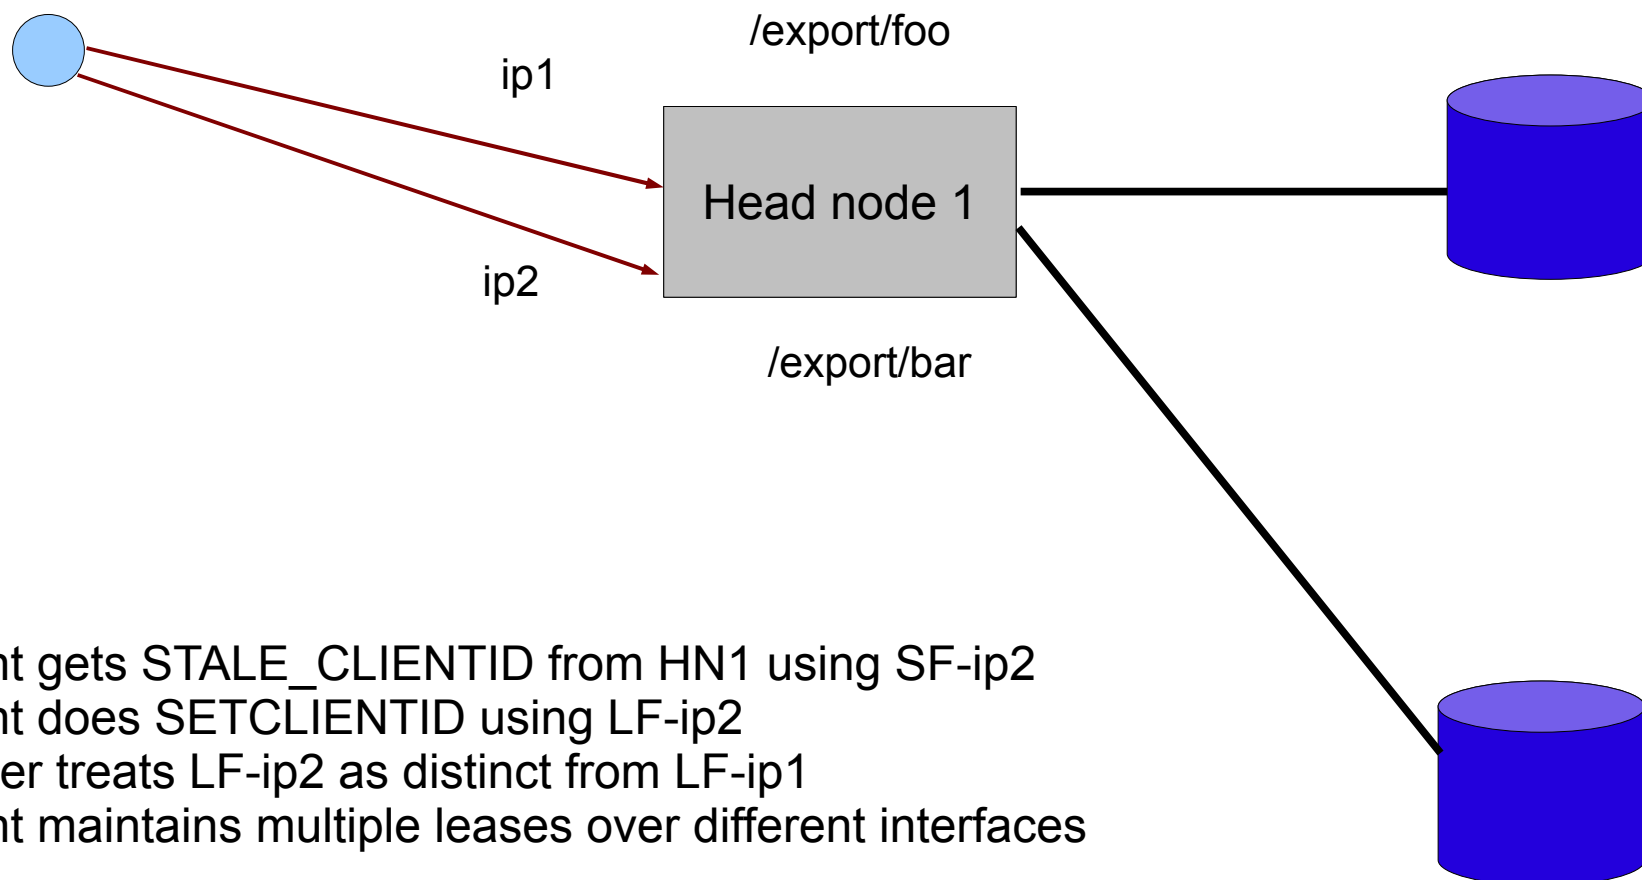

Clients recover state for "bar"
Clients accessing "foo" unaffected

Oracle ZFSSA active/active mode, single client accessing both

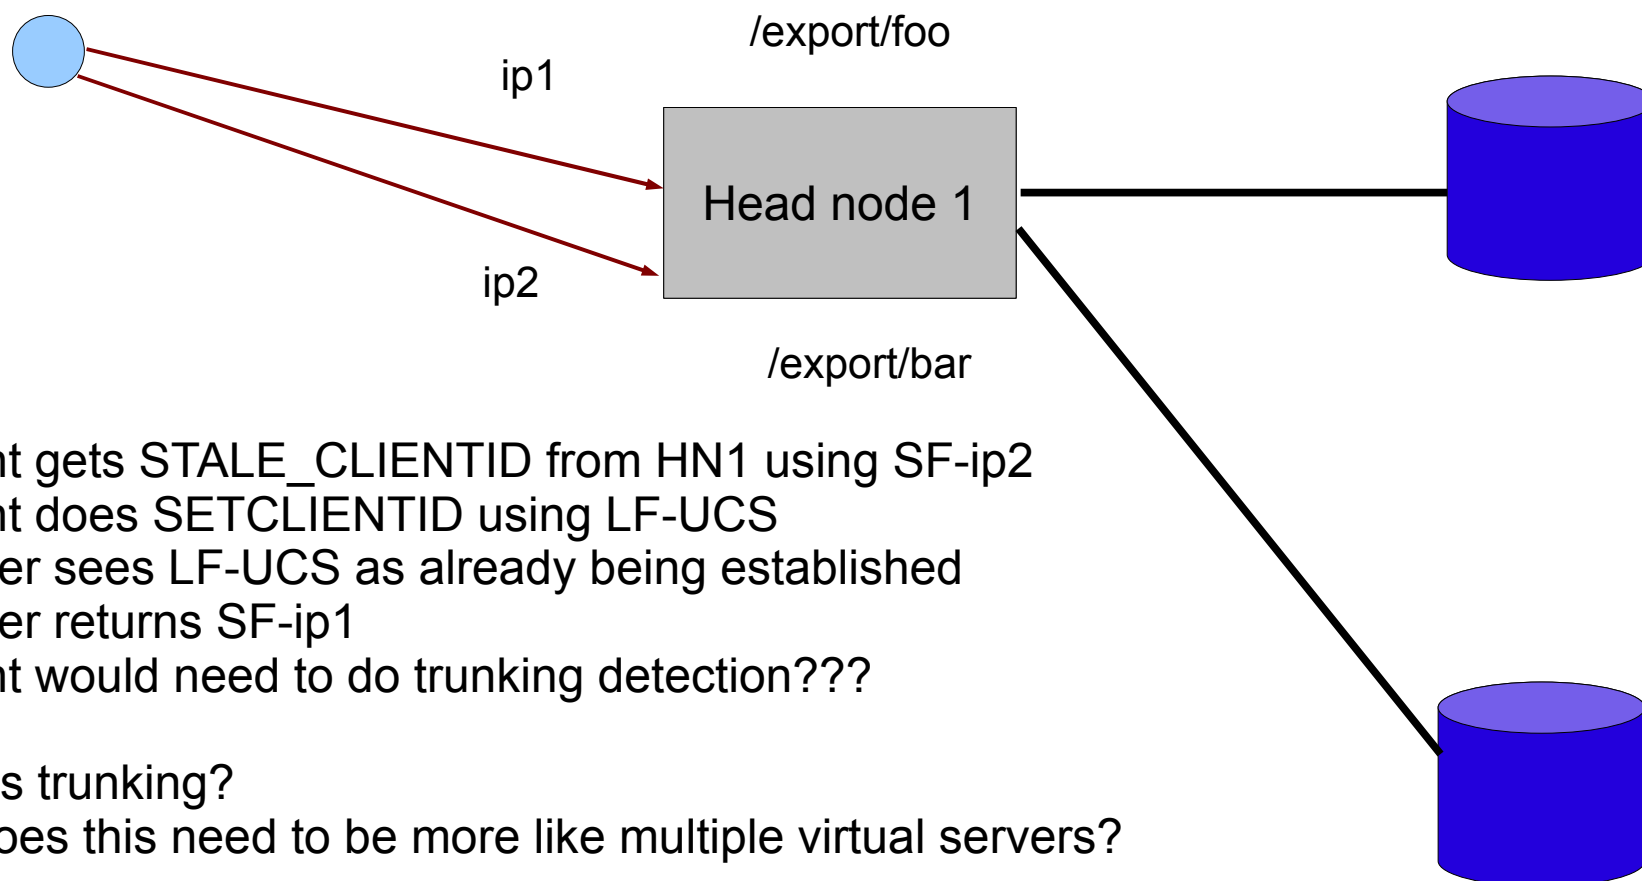

Non-UCS client presents
Itself as 2 distinct clients,
Due to server IP being embedded in the CID long form

Oracle ZFSSA active/active mode, single client accessing both, after take over

Client gets STALE_CLIENTID from HN1 using SF-ip2
Client does SETCLIENTID using LF-ip2
Server treats LF-ip2 as distinct from LF-ip1
Client maintains multiple leases over different interfaces

Oracle ZFSSA active/active mode, UCS client accessing both, after take over

Client gets STALE_CLIENTID from HN1 using SF-ip2
Client does SETCLIENTID using LF-UCS
Server sees LF-UCS as already being established
Server returns SF-ip1
Client would need to do trunking detection???

Is this trunking?
Or does this need to be more like multiple virtual servers?

Conclusion: UCS clients affect server IP address takeover

What do other servers do?
